How Much Symmetry Knowledge Does Decoding Need?

Syndrome, Z(N) charge and SU(N) irrep records on a honeycomb patch

1. Objective

An error on an edge creates a fundamental V of SU(N) at one endpoint and its conjugate $\bar{V}$ at the other. Which endpoint receives V is random and never observed. Detectors may reveal three nested levels of information about what has arrived: only the parity, also the $\mathbb{Z}_N$ charge, or the full SU(N) irrep. Determine how optimal logical recovery depends on the level of information and on N.

The principal result is a phase diagram with $p \in [0, 1]$ on the horizontal axis and $N = 2, \ldots, 8$ on the vertical axis, showing the boundary between decodable and non-decodable regions separately for each of the three records. Section 5 states the required results; each is checked against an independent reference.

The model below is a stipulated classical noise-and-observation channel. Conditional independence of the local readouts, given the microscopic configuration, is part of the definition.

2. Geometry and logical recovery

For integer $L \geq 2$, the vertices are (i, j) with $0 \leq i \leq 2L - 1$ and $0 \leq j \leq L$. Retain the horizontal edge $((i, j), (i + 1, j))$ for $0 \leq i \leq 2L - 2$ and $1 \leq j \leq L - 1$. Retain the vertical edge $((i, j), (i, j + 1))$ exactly when $0 \leq j \leq L - 1$ and $i + j$ is even. Discard vertices with no retained edge. This is a brick-wall honeycomb patch.

The rows $j = 0$ and $j = L$ are open (rough) boundaries; their vertices have degree one and are not measured. All vertices with $1 \leq j \leq L - 1$ are measured detectors. The columns $i = 0$ and $i = 2L - 1$ are closed (smooth) boundaries made of detectors. The shortest path between the open boundaries has $2L - 1$ edges.

Let H be the detector-edge incidence matrix over $\mathbb{F}_2$, and let Γ_T contain exactly the edges meeting the top row $j = L$. For a binary edge vector z, define

$$\ell(z) = \bigoplus_{e \in \Gamma_T} z_e.$$

A decoder returns a binary correction c. On error vector x, it succeeds exactly when $Hc = Hx$ and $\ell(x \oplus c) = 0$.

3. Noise and the three records

Independently on each edge, draw $x_e \sim \text{Bernoulli}(p)$. For each active edge, independently choose one endpoint with probability $1/2$; it receives V and the other endpoint receives $\bar{V}$. At detector v, let a_v and b_v be the numbers of V and $\bar{V}$ received, and $s_v = (a_v + b_v) \bmod 2$.

Conditional on the microscopic configuration, each detector independently yields an irrep R_v of SU(N) with

$$P(R_v = R) = \frac{m_R(a_v, b_v)\dim R}{N^{a_v+b_v}},$$

where $m_R(a,b)$ is the multiplicity of R in $V^{\otimes a} \otimes \bar{V}^{\otimes b}$. Labels are isomorphism classes of SU(N) irreps. For example, $(a,b) = (1,1)$ gives the trivial irrep with probability $1/N^2$; at $N = 2$, $n_v = 2$ gives total spin 0 or 1 with probabilities $1/4$ and $3/4$.

The three records, all given together with (G_L, p, N), are:

Record	Decoder-visible information
O_0	syndrome s
O_1	s and the charges $k_v = (a_v - b_v) \bmod N$
O_2	s and the irreps R_v

No decoder receives x, the orientations, a_v, b_v, or anything at the open boundaries. There is one round and no measurement error.

4. Optimal recovery

For record type O_r and an observed record o, let $Z_\lambda(o)$ be the total probability of all microscopic configurations, including orientations and readout outcomes, that produce o and have $\ell(x) = \lambda$. The optimal decoder chooses the larger of Z_0, Z_1. Its unconditional logical error rate is

$$R^*_{r,L}(p,N) = \mathbb{E}_o\left[\frac{\min(Z_0, Z_1)}{Z_0 + Z_1}\right],$$

averaged over the physical record law. For a fixed record type and N, a value of p is decodable if $R^*_{r,L}(p,N) \to 0$ as $L \to \infty$, and non-decodable if it stays bounded away from zero.

5. Required results

R1. Phase diagram. For each record O_0, O_1, O_2 and each $N \in \{2, \ldots, 8\}$, give the decodable set in $p \in [0,1]$ as a union of intervals. Give each interior endpoint with an uncertainty, to within ± 0.01 of the reference, or mark it unresolved with the bound you can support. Draw the three boundaries on one (p, N) diagram.

R2. Exact structure. State and prove every exact property of the three records that your phase diagram relies on, such as exact solvability, orderings or equivalences.

R3. Large N. For O_2, give an explicit integer N_0 with a proof that every $p \in [0, 1]$ is decodable for all $N \geq N_0$, or prove that no such N_0 exists. A smaller valid N_0 is better.

R4. Exact posterior. For O_1 and O_2, provide a routine that returns $Z_0/(Z_0 + Z_1)$ for any supported record, exact up to floating-point rounding or with certified bounds. It will be tested on held-out records with $L \leq 4$ and $N \leq 8$, with tolerance 10^{-9}.

6. Evidence

Phase assignments must rest on size dependence across increasing two-dimensional patches, not on one crossing or one low failure count. Validate every inference method against an independent enumeration on small patches. Keep every attempted trial in the unconditional denominator; an exception or invalid correction is a failure. Separate statistical, finite-size and approximation uncertainty, and show that approximation error cannot change any R1 answer.

7. Deliverables and resources

Submit `answers.json` with keys `R1` (for each record and N: list of intervals with endpoint uncertainties, or `"unresolved"` with bounds) and `R3_N0` (integer or `null`). Submit a concise report with the phase diagram, the proofs for R2 and R3, the evidence, and the limitations, together with source, data, an environment specification, and commands that reproduce every number and figure.

Provide documented callables `posterior(graph, p, N, record_type, record)` for R4 and `decode(graph, p, N, record_type, record, rng=None) -> correction`, with documented graph and array conventions.

Use one workstation with at most 8 CPU cores and 32 GiB RAM; no GPU. Report resources, seeds and stopping rules. Internet access and standard scientific libraries are allowed. No method is prescribed.
